ABSTRACT

Background: First trimester vaginal bleeding (FTVB) plays a role in occurrence of late pregnancy complications in both mother and infant. Late pregnancy outcomes in mothers and infants are the main concerns for the obstetricians. The purpose of this study was to assess the perinatal outcome of pregnancies complicated by first trimester vaginal bleeding.

Methods: The present study included total 100 singleton pregnant women with history of FTVB whose pregnancy was confirmed chemically. Patients were closely observed and follow up done 2 weekly upto 36 weeks and weekly after that. Late pregnancy outcomes such as gestational hypertension, pre eclampsia, placental abruption, preterm delivery and pre mature rupture of membranes in the mothers and low birth weight, intrauterine growth restriction, apgar score after 1 and 5 minutes, and NICU admission in new born were calculated.

Results: Incidence of PROM, gestational hypertension and placental abruption is more in women with FTVB. However there infant had higher rate of IUGR and LBW. Apgar score after 1 and 5 minutes was less than 5 and admission to NICU too.

Conclusions: FTVB is an important factor to predict both the maternal and fetal outcomes in late pregnancy. It is therefore important to evaluate and consider these pregnancies as high risk group and provide careful antenatal care.

Keywords: FTVB, Preterm labour pain, Pregnancy outcome

INTRODUCTION

First trimester bleeding per vaginum is one of the most common obstetric problems, complicating 16- 25% of all pregnancies.1 Vaginal bleeding in the first trimester of pregnancy is associated with ectopic pregnancy, abortion (threatened, inevitable, incomplete or complete), implantation of pregnancy, hydatiform mole and cervical pathology. Threatened abortion is presumed when a bloody vaginal discharge or bleeding appears through a closed cervical os during first half of pregnancy. Approximately half of these pregnancies will abort, although the risk is substantially lower if foetal cardiac activity is visualised. Vaginal bleeding is associated with a twofold increased risk of other complications during that pregnancy.4,5 There is increased risk of suboptimal pregnancy outcome in the form of preterm deliveries, low birth weight and unexplained intrauterine death in these cases.6-14 The present study aimed to evaluate the perinatal outcomes in a pregnant women with a history of vaginal bleeding in the first trimester of their pregnancy.
METHODS

We examined 100 singleton pregnant women with first trimester bleeding per vaginum, who came to the Department of Obstetrics and Gynaecology in our institute during 2013-15 and whose pregnancy was confirmed by urine pregnancy test. After taking an informed consent, patient were kept under surveillance until delivery and the consequences of pregnancy were evaluated by close observation and follow up.

Inclusion criteria

Singleton pregnancies complicating with FTVB (<14 weeks) with positive cardiac activity detected with ultrasound.

Exclusion criteria

- Hydatiform mole
- Cervical pathology
- Women with chronic medical complications including diabetes, hypertension, cardiac disease, hepatic disease
- Bleeding disorders
- Any evidence of foetal anomaly
- Women with history of infertility
- Multiple pregnancies

Follow up were done every 2 weekly upto 36 weeks and weekly after that. Foetal growth was monitored closely by clinical examination and repeat ultrasound scan at 6-8 weeks interval. Late pregnancy complications were evaluated in two categories of maternal and foetal complications. Maternal complications included PROM, PTLP, APH, gestational hypertension, preeclampsia. Foetal complications included LBW, IUGR, APGAR score 1 after 5 minutes of delivery, Live birth or Pregnancy loss.

RESULTS

In present study, 100 cases of FTVB were studied. Majority of patients (70%) presented with spotting, out of which 62 (88.5%) had a viable pregnancy and only 8 (11.4%) had abortion. 16 (80%) out of 20 patients with moderate bleeding in first trimester had abortion. All of 10 patients with heavy bleeding per vaginum during first trimester had abortion.

Over all 34% cases with FTVB were aborted and rest 66% pregnancies continued beyond 20 weeks of gestation.

<td>9</td>
<td>14%</td>
</tr>
<tr>
<td>IUD</td>
<td>5</td>
<td>7%</td>
</tr>
</tbody>
</table>

In foetal outcome 55% patients delivered full term, 24% delivered preterm, 14% had IUGR, and 7% had IUD.
30.6% new born had NICU admission and 37.8% had low birth weight (LBW).

DISCUSSION

First trimester bleeding per vagina is not only associated with abortion but also with a higher rate of pregnancy complications. The present study shows that women with first trimester bleeding per vagina and continued beyond 20 weeks of gestation are at increased risk of later complications such as preterm delivery, PROM, lower gestational foetal weight.15,17 Because of impaired implantation and inadequate invasion of trophoblasts, spontaneous abortion may occur in early pregnancy while preterm delivery, PPROM, placental ablation and preeclampsia may happen in late period.16,18,19

Preterm delivery and PPROM rates were increased in this group of patients because of increased free iron deposits from subchorionic bleeding, hydroxy radical is catalysed damaging the membrane.17,18

The other point in PPROM etiology is the chronic inflammatory reaction within the decidua and placental membranes which causes rupture of the membranes, decidual thrombosis, ischaemia and necrosis results in vaginal bleeding along with inflammatory response and thrombosis formation. Thrombin is a uterotonic agent and may cause preterm labor during late pregnancies and spontaneous abortion during early weeks of gestation.1

Both preterm delivery and PPROM leads to low birth weight. Neonatal intensive care unit admission for low birth weight foetuses were increased because of prematurity complications such as respiratory distress.1,17 Bleeding amount and characteristics are related with poor maternal and foetal outcome.

CONCLUSION

Concluding the result of present study, first trimester bleeding can be a predicting factor for late trimester pregnancy outcome; both maternal and foetal outcomes. It is therefore necessary to consider these pregnancies as a high risk group for which antenatal care should be performed carefully.
