ABSTRACT

Background: Cervical cancer is very common in developing countries. In Uttar Pradesh the literacy rate of women is low as compared to other states of India. Poverty is very high. Most women report with advance stage of cervical cancer. It can be prevented by early screening with Pap smear. Aim of our study is to know about the awareness of Pap smear and cervical cancer vaccine among women attending a tertiary hospital in Eastern part of Uttar Pradesh India.

Methods: A questionnaire based study is done on 1500 patients attending the OPD and admitted in ward over a period of one year.

Results: To our surprise only 12.06% women were aware of Pap screening test. Only 6.13% women were aware of cervical cancer vaccine. The awareness about both Pap test and cervical cancer vaccine was present in only 5.2% only. The education of the women and socioeconomic status also play an important role. The awareness among rural women was significantly less as compared to urban women.

Conclusions: The awareness about Pap test and cervical cancer vaccine was very low specially in women staying in rural area. So if we really wanted to reduce cervical cancer then we have to increase the awareness among women by media, camps etc.

Keywords: Pap smear, Vaccine, Awareness

INTRODUCTION

Cervical cancer is very common in developing countries. India accounts for 1/5th of the burden of cervical cancer.1 According to WHO2 80% deaths from cervical cancer were from developing countries. In the developed countries because of screening the incidence of cervical cancer has reduced. Pap smear test is very simple and cost effective test for cervical cancer screening. Pap smear screening has sensitivity of 50-75% and specificity of 98-99%.

But in developing country like India because of illiteracy and poverty awareness is very low. Few states of India like Uttar Pradesh, Bihar and Madhya Pradesh are far less developed than rest of country. Study was conducted in Eastern part of Uttar Pradesh where poverty and illiteracy is very high. Most of the patient in our tertiary hospital report in advance stage of cervical cancer. This can be prevented by screening and diagnosing early. The aim of this study was to know how much awareness about Pap test and cervical cancer vaccine among patients attending gynaecology OPD and ward at a tertiary care hospital.

METHODS

A prestructured questionnaire was filled by asking from the patients. This study was conducted in SSH hospital of institute of medical sciences BHU Varanasi, Uttar Pradesh.

DOI: 10.5455/2320-1770.ijrcog20150430
Pradesh India. Total 1500 patients attending gynaecology OPD and inpatients and the female attendants were also enrolled. This study was done for one year.

We observed how many patients are aware of Pap test and cervical cancer vaccine. We also recorded the education status and socioeconomic status of patients. It is also noted whether the patients belong to rural area or urban area.

RESULTS

Total 1500 patients observed over a period of one year. The overall awareness among patients about Pap test was only 12.06% (Table 1). Out of 1500 patients 640 belonged to urban area and 860 belonged to rural area. The awareness about Pap test among rural women was only 3.95% as shown in Table 2.

The socioeconomic status and education level also plays an important role. As we can see in Table 3 the awareness about Pap test among graduate women was 21.66% while among illiterate was only 3.23%. The women with yearly income >2 lakh were more aware than with income less than one lakh/year as shown in (Table 4).

DISCUSSION

Inspite of high incidence of cervical cancer in India there are no proper screening programme for cervical cancer. Today also maximum patient report with advance stage of cervical cancer. In our study we had shown that awareness about cervical cancer screening by Pap test is very low specially among rural women. It has been seen from the population based cancer registers that cervical cancer is on decline but rates are still too high mainly in rural areas, and the absolute number has increased due to population growth.3

Indian study done by Singh E et al. among nursing staff had shown that 96% respondents had heard about Pap smear.4

A study from Turkey was done by Ertem indicates that all respondents had heard about Pap smear. But in our study only 12.06% of patients had heard about Pap test and only 6.03% of women had heard about cervical cancer vaccine. A study done in Karnataka (India) by Montgomery et al. had shown that 36% of women had heard of HPV and only 5% of women reported to have Pap smear. We should not lose any opportunity to screen women whenever they visit hospital for any problem.

In our study we had seen that educational status and socioeconomic status also play an important role. Rural women were less aware as compared to urban women.

**CONCLUSION**

The awareness of cervical cancer screening, vaccine for cervical cancer prevention is very low in this part of India especially in poor, illiterate women living in rural areas. To prevent cervical cancer we should make women aware with the help of mass media, health camps. We should also educate these women about how simple and effective is the Pap test. We should also teach paramedical staff about the importance of Pap test.
