ABSTRACT

Background: Cardiac disease is an important cause of maternal mortality and morbidity both in antepartum and postpartum period. The overall incidence of heart disease in pregnancy is <1%. Objective of present study was to determine maternal outcome in pregnant women with heart diseases in terms of fetal complication, maternal complication and Mode of delivery.

Methods: This study was conducted in the Department of Obstetrics and Gynaecology at Government Lalla Ded Hospital, an associated of Government Medical College, Srinagar which is the sole tertiary care referral centre in the valley. 90 women with heart disease which were previously established or diagnosed during pregnancy were enrolled in the study.

Results: In 90 women pregnancies was complicated by heart disease in the study. The prevalence of heart disease amongst all pregnancies found in hospital was 4.3%. The principal cause of cardiac lesion was Rheumatic heart disease (RHD) (56.6%) while congenital heart disease was seen in 13.3%. Among the women who had RHD, mitral stenosis seen in 21 (23.3%) was most common lesion and Multiple cardiac lesions 21 (24.4%) women. Among the women with congenital cardiac disease, mitral valve prolapse was most common constituting 5 (5%) cases. Cardiomyopathy was the most common constituting 7 (7.3%). Heart failure developed in 10 (11.1%) whose NYHA class changed from class I/II to class III/IV. Majority of the women delivered by caesarean section 33 (35.6%) while (35.6%) had a normal vaginal delivery with spontaneous onset of labour. 7% had assisted instrumental vaginal delivered. 9% women had first trimester abortion. There were 4 maternal deaths. 85.6% live births were observed in these women. No baby had congenital heart disease. 72.8% babies born weighed more than 2kg.

Conclusions: This study concluded that pre-pregnancy diagnosis, counselling, appropriate referral, antenatal supervision and delivery at equipped centre improve the pregnancy with heart disease outcome for both mother and baby.

Keywords: Cardiomyopathy, Mitral valve stenosis, Pregnancy, Rheumatic heart disease

INTRODUCTION

Cardiac disease is one of the important cause of maternal mortality and morbidity both in antepartum and postpartum period. Cardiac disease in pregnancy is broadly divided into congenital and acquired. The acquired group includes RHD, cardiomyopathies and ischemic heart disease. Of these, in developing countries rheumatic heart disease is the commonest type, whereas cardiomyopathies and congenital heart disease one more common in developed countries. Among all presentations of Rheumatic heart disease, mitral stenosis is the predominant lesion and accounts for nearly three quarters of all cases.
Cardiomyopathies are being increasingly recognized with three main types – the dilated (including peripartum cardiomyopathy), restrictive and hypertrophic variety. The overall incidence of heart disease in pregnancy is <1%. The presence of maternal heart disease effects on the fetus in a number of ways. The risk of spontaneous miscarriage and therapeutic abortion increases in women with heart disease. The children borne from the mother with congenital heart disease are at increased risk of congenital heart disease. The overall risk of inheriting polygenic cardiac disease is 3-5%, as compared to 1% risk in the general population. This risk is dependent on the condition of affected parent and there is an increased risk if a previous siblings are affected. Some cardiac medications can have adverse effects on the fetus such as ACE inhibitors, warfarin and statins. ACE inhibitors well known for the teratogenic effects especially during first trimester and should therefore be avoided during this period. Exposure during second and third trimester can lead to marked fetal hypotension and decreased renal blood flow. If the use of ACE inhibitors is necessary, the lowest possible dose should be used and amniotic fluid levels and fetal growth should be monitored carefully. The use of Statins during pregnancy is controversial. However, epidemiological data suggests that statins are not major teratogens. So, it is still advisable to avoid statins during the first trimester. The relative immunocompromised state of pregnancy increases the risk of infection (e.g. urinary tract infection). This can increase the heart rate, potentially worsening cardiac function. Approximately, 1% of all pregnancies are complicated by cardiovascular diseases.

Cardiovascular abnormalities are considered most important non-obstetric cause of morbidity and mortality during pregnancy. In women of childbearing age, Rheumatic and Congenital heart diseases are currently the most frequently found cardiovascular diseases. In developed countries, the prevalence of pregnancy complicated by rheumatic heart disease (RHD) has decreased. Previous ratio of 3:1 for RHD to congenital heart disease complicating pregnancy is now essentially reversed but in developing countries rheumatic heart diseases are still predominant and continues to be a major cause of maternal morbidity and mortality. In western countries, maternal heart diseases are the third most common cause of maternal death and complicates 1-3% of pregnancies. Cardiac diseases can complicate 1-4% of pregnancies in women without pre-existing cardiac abnormalities. Cardiac disease is one of the three major indirect causes of maternal mortality in India. Pregnancy can cause certain therapeutic problems, which may threaten maternal and fetal well-being and survival.

The circulatory changes of pregnancy in the presence of maternal heart disease may result in adverse consequences even death of the mother or fetus. Pregnancy is a challenge to women with heart disease because of the 50% increase in plasma volume and six-fold increase in the risk of thrombosis. In developing countries, a large number of women become pregnant prior of seeking therapeutic intervention for cardiac lesions and many of them are only diagnosed with heart disease during pregnancy. Detailed assessment of patient throughout pregnancy may lead to initial discovery of heart disease. If diagnosed early, and managed properly with multidisciplinary approach, collaboration of a team of trained obstetricians, cardiologist, anaesthetist, pediatrician and nurse, it results in successful outcome for mother and child in majority of cases.

In women with normal reserve, Hemodynamic changes of normal pregnancy are well tolerated. However, decompensation occurs in diseased heart, with resultant increase in maternal morbidity and mortality. It is natural to expect that fetus will also be compromised in these mothers as fetal health depends upon adequate and continuous supply of well oxygenated maternal blood. In western countries, maternal cardiac disease complicates 1-3% of pregnancies and is the third common cause of maternal death during pregnancy. Cardiac diseases complicate 1-4% of pregnancies in women without pre-existing cardiac abnormalities. Heart disease is one of the 3 major indirect causes of maternal mortality in India. Most data concerning pregnancy course in heart disease patients are anecdotal reports or are in small series; only a few comprehensive studies are available. The primary objective of the present study is to assess the effect of heart disease in pregnancy and its outcome.

**METHODS**

This study was conducted in the Department of Obstetrics and Gynecology at Government Lalla Ded Hospital, an associated of Government Medical College, Srinagar which is the sole tertiary care referral centre in the valley. 90 women with heart disease which were previously established or diagnosed during pregnancy were enrolled in the study. Included in our study were all pregnant women with congenital or acquired cardiac lesions or delivered patients with heart disease who were referred to our hospital but those with associated medical disorders like Diabetes mellitus, pulmonary disease, renal disease or any other endocrinological disease were excluded from this study. A structured detailed proforma was used to gather the essential information regarding heart disease in pregnancy. Baseline data recorded included were age, parity, gestational age, cardiac lesions, use of cardiac medications, thorough clinical examination including chest and cardiovascular auscultation, ECG and echocardiographic assessment of left and right ventricular systolic function. The mode of delivery whether vaginal, use of instruments and the need for LSCS was duly recorded.

**RESULTS**

A total of 90 women where pregnancy was complicated by heart disease were included in the study. The
The prevalence of heart disease amongst all pregnancies found in the hospital was 4.3%. The age of patients ranged from 20-35 years with maximum number of patients in 20-30 years age group (74.5%). In this study, most of the patients were primigravida (60%). The Rheumatic Heart disease was the principal cause of heart disease amongst all pregnancies. Congenital heart disease was present in 13.3% patients.

Among the women who had Rheumatic heart disease, Mitral Valve stenosis being the most common lesion and was seen in 21 (23.3%). Multiple cardiac lesions were present in 22 (24.4%) women. Among the women with congenital cardiac disease, mitral valve prolapse was present in 21 (24.4%) women. Among the women who had Rheumatic heart disease, Mitral Valve stenosis was the most common lesion constituting 5 (5%) cases.

Cardiomyopathy was the most common cardiac disease in the miscellaneous group, constituting 7 (7.8%). Among the studied pregnant women with heart disease, heart failure developed in 10 (11.1%) cases whose NYHA class changed from class I/II to class III/IV. Majority of women delivered by cesarean section 33 (36.7%). Thirty-two (35.6%) subjects had a normal vaginal delivery with spontaneous onset of labour. Seven (7%) had assisted instrumental vaginal delivery.

DISCUSSION

This study was conducted in the postgraduate Department of Obstetrics and Gynaecology, Lalla Ded hospital affiliated with GMC, Srinagar in total of 90 women. This study aimed at assessment of maternal and neonatal complications associated with cardiac disease in pregnancy. Various studies estimated that 0.3% to 3.5% of all pregnancies are complicated by heart disease. In the present study, the prevalence of 4.3% was found which was same as that of the study conducted by Puri S et al. In the current study, majority of the patients were in the age group of 20-30 years (74.5%) and most of them were either primigravidae or primipara (60%). This was comparable to Vidyadharet al were 70% were either primigravidae or primipara.

In the current study, RHD (56.6%) was the principal cardiac lesion and mitral stenosis was the most common cardiac lesion (23.3%). These results were in consensus with Vidyadharet al, Mazhar SB et al, Devabhaktula et al, and N Bhatla et al. However incidence of RHD has been greatly reduced in developed countries by widespread use of antibiotics effective against the streptococcal infections. Thus, current study indirectly indicates inadequate treatment of streptococcal infections in childhood and adolescence. Echocardiography was done routinely in our patients. Twenty-two (24.4%) patients had multiple cardiac lesions. Echocardiography was helpful for early and accurate evaluation of cardiac lesions.

In this study, 35.6% women had spontaneous vaginal delivery as compared to 41% (Nilajkumar et al); 24% (Alireza et al); 76.2% (Mazhar et al); 73.5% (Hameed et al); 62.8% (Vidyadharet al) in other studies. Cesarean Section (36.7%) was done only for obstetrical indications. Nilajkumar et al reported caesarean in 20.6%; 9.5% by Mazhar et al; Alireza et al (76%); 21,24,25 In the present study, 55 of women underwent labour...
induction as compared to 15% in study conducted by Hameed et al and Pratibha D et al. In the evaluation of pregnancy with cardiac disease, 7.8% of patients had inevitable abortions and 2.2% had to undergo MTP which was comparable to Suman et al and Mazhar et al studies. Mortality in pregnant females with cardiac disease is mainly due to cardiac failure and pulmonary oedema. Four females in our study died mainly due to cardiac failure, sepsis and shock which was comparable to Hameed et al, Mazhar et al, Alireza et al, Verena et al, Akhtar et al and Sheetal CN et al.

In the present study, 21 (27.8%) babies were born who weighed less than 2 kg 56 babies. Seventy-seven live births were observed in these women and 13 still births which was comparable to Mazharet al.

CONCLUSION

Present data supports the fact that the prognosis of pregnant women with heart disease has improved, leading frequently to successful outcome. Proper evaluation of maternal prognosis prior to conception and adequate clinical follow up during pregnancy are both fundamental measures for obtaining a satisfactory outcome in these patients. This study concluded that pre-pregnancy diagnosis, counseling, appropriate referral, routine antenatal supervision and delivery at an equipped centre improve the pregnancy with heart disease outcome for both mother and baby. Cardiac failure is a serious complication and often leads to maternal death. We therefore stress the need to monitor cardiac patient for early detection and management of heart failure throughout the course of pregnancy, labor and puerperium.
