### ABSTRACT

**Background:** Changes in bone mineral density during pregnancy are not widely studied because of the risk of radiation hazard to the fetus. But newer technology like DEXA has made it possible to measure bone density accurately with low dose radiations which are safe even during pregnancy. The aim of this study was to evaluate the changes in maternal bone turnover markers and bone mineral content at forearm during pregnancy.

**Methods:** A total of 32 pregnant women with singleton pregnancy of more than thirty five weeks gestational age and thirty non-pregnant, non-lactating women as controls were recruited. Baseline blood investigations, serum calcium, serum alkaline phosphatase and DEXA of the forearm at ultra-distal, mid radius and proximal 1/3<sup>rd</sup> of radius were done at the time of recruitment into the study.

**Results:** Bone mineral density of forearm of pregnancy group was compared with non-pregnant, non-lactating control group to see the effect of pregnancy. Bone turnover markers like serum calcium and serum ALP were also compared among pregnancy group and controls. The mean bone mineral density of controls at ultra-distal radius was  $0.437 \pm 0.058 \text{ g/cm}^2$ , while in pregnant women it was  $0.431 \pm 0.058 \text{ g/cm}^2$  that was not statistically significant. Bone mineral density at mid radius in control was  $0.599 \pm 0.051 \text{ g/cm}^2$  and in pregnant women it was  $0.597 \pm 0.048 \text{ g/cm}^2$  with no significant difference. BMD at proximal 1/3<sup>rd</sup> radius in controls was  $0.670 \pm 0.036 \text{ g/cm}^2$  as compared to pregnant women where it was  $0.660 \pm 0.036 \text{ g/cm}^2$  without any statistical significance. Total BMD at forearm in control and pregnant women was  $0.586 \pm 0.035$  and  $0.582 \pm 0.036$  respectively and again there was no statistically significant difference.

**Conclusions:** There is no significant impact of pregnancy on bone mineral density of forearm. Although more bone areas need to be investigated for the further confirmation.

**Keywords:** Bone mineral density, DEXA, Forearm, Pregnancy, Radius

### INTRODUCTION

Bones not only provide mechanical support and decide the attributes of body size and shape but also play a very vital role in calcium and phosphorus homeostasis. Bone is a special connective tissue which is made up of organic matrix (35%) composed of bone cells and the collagen protein and inorganic matrix (65%) which is calcium

hydroxyapatite. Calcium hydroxyapatite contains 99% calcium of the whole body. Bone is continuously kept on forming and resorbing and this process of bone formation and resorption is strictly controlled by multiple factors. When bone formation predominates then bone mass increases and when resorption predominates then bone mass decreases. Their balance determines bone mass at any point of time. BMD is predominantly determined by

genetic factors and partly by environmental factors like pregnancy and lactation. Weight, BMI and lean body mass, fat content, physical activity are other factors which may also influence BMD. During pregnancy there is weight gain leading to increased mechanical load on maternal skeleton. There is also increase in fat content which leads to peripheral production of oestrogen, these factors affect bone mineral deposition in positive way.

Peak bone mass is probably most important determinant of risk of developing osteoporosis later in life. It is usually attained in third decade of life and at this time, bone formed and bone reabsorbed remain in equilibrium. After the age of thirty; the amount of bone resorbed exceeds than that what has been formed and there is a steady fall in the skeletal mass. Any disturbance in this equilibrium i.e. too fast resorption or too sluggish replacement results in osteopenia/ osteoporosis. Theoretically pregnancy is the time of physiological burden on calcium homeostasis as on one hand there is increased requirement for the developing foetus and on other hand there is increased demand for growing maternal tissues also. The developing foetus draws around 30gm calcium from the mother during entire pregnancy period; theoretically placing the mother at an increased risk for osteoporosis/osteopenia.<sup>1</sup> Increased concentration of parathyroid hormone related peptide (PTHRP) is detected in the maternal circulation during pregnancy, probably originating from foetal, placental or mammary tissue. PTHRP can activate PTH / PTHRP receptors and can increase osteoclastic activity. It may contribute to rise of 1,25 dihydroxy vitamin D levels and may protect bones by inhibiting levels of PTH. Serum calcitonin levels are also show rise during pregnancy and they are produced by thyroid, breasts and placenta. They protects maternal skeleton from excessive bone resorption.<sup>2</sup>

During pregnancy, intestinal calcium absorption increases to meet much of the foetal calcium needs. The body also responds to increased foetal calcium demand by increasing total 1,25 dihydroxy vitamin D levels through up regulation of renal hydroxylation, extra renal synthesis or both in placental or foetal tissue.<sup>3</sup> The third trimester oestrogen surge is also protective to bones.

We performed a cross sectional observational study to evaluate these changes in maternal bone metabolism by examining various parameters of bone metabolism like bone mineral density, serum alkaline phosphatase and serum calcium. We tried to find out co-relation of pregnancy with these changes in parameters.

## METHODS

This was a cross-sectional observational case control study conducted on 32 pregnant women above eighteen years of age with singleton pregnancy with thirty five weeks or more gestational age and age-matched 30 non pregnant-non lactating controls attending an outpatient clinic at a tertiary care hospital for routine antenatal care

and other gynaecological problems. The study was approved by the institutional ethical committee and written informed consent was obtained from all participating women. Study was conducted from April 2018 to December 2018. Women were thoroughly asked for any past medical or surgical history or drug history which could affect bone metabolism.

Exclusion criteria included women who had been pregnant or lactating in last 2 years, any metabolic and endocrinopathy affecting bone metabolism like mal-absorption, hyperthyroidism, hyper parathyroidism, Cushing disease, acromegaly, multiple pregnancy; systemic diseases like cardiac, hepatic or renal disease; women having radiation exposure, malignancy of bone or metastasis to bone; any other bone disease, fracture, prolonged immobilization due to any cause and musculo-skeletal disorder. Subjects consuming drugs which are known to affect bone metabolism eg. hormones, corticosteroids, heparin were also excluded. Women included in the study were thoroughly interrogated for their obstetrical as well as gynaecological history regarding parity/gravidity, spacing between child births, complications in previous or present pregnancy like multiple pregnancy, number of children breast fed, average duration of breast feeding, mode of delivery, birth weight of baby etc. Disorders of menstruation or history of fibroid or any other gynaecological condition which show hyperestrogenism or affect hormonal balance were enquired. Past surgical history especially bone surgeries, bowel surgery and neck surgeries were excluded. Hormonal contraceptive usage was asked. Dietary history was asked in detail for dairy products consumption and calcium supplementation and total daily calcium consumption was calculated.

A thorough general examination was done with special attention to height, weight, BMI, icterus & lymphadenopathy. Systemic examination especially of musculo-skeletal, endocrinial, respiratory, central nervous and cardiovascular system was done to rule out any systemic disease. Detailed obstetrical/ gynaecological examination was done in each case. All baseline blood investigations were done at the time of recruitment into the study.

In pregnancy group DEXA of forearm was done once at the gestational age > 35 weeks after providing lead apron to the women. Three regions were specially looked for bone mineral density i.e. ultra distal radius (mainly cancellous), mid radius, proximal 1/ 3<sup>rd</sup> radius (mainly cortical).

Serum calcium, serum albumin, serum alkaline phosphatase and serum thyroid stimulating hormone estimation was done once after inclusion into the study.

Bone mineral density was measured by DEXA using digital flash beam technology using collimated x-ray source to get a cone shaped beam of a bi-dimensional

detector (2D detector). Bone mineral density was noted in gm/cm<sup>2</sup> and T- score and the results were interpreted as below.

T score	Interpretation
-1 or higher	Normal
-1 to -2.5	Osteopenia
-2.5 or lower	Osteoporosis

Z-score is defined as difference between the patient's values and the mean value in a population of healthy subjects of same age, divided by the standard deviation. For women in reproductive age group T-score and Z - scores are same.

#### Statistical analysis

The results in two groups were compared using chi-square test and student t- test. P value <0.05 was considered statistically significant.

#### RESULTS

There was no statistically significant difference between the two groups as far as demographic profile was

concerned (Table 1). The mean bone mineral density of controls at ultra-distal radius was  $0.437 \pm 0.058$  g/cm<sup>2</sup>, while in pregnant women it was  $0.431 \pm 0.058$  g/cm<sup>2</sup>. There was 1.4% fall in BMD in pregnant women at ultra-distal radius but that was not statistically significant. Bone mineral density at mid radius in controls was  $0.599 \pm 0.051$  g/cm<sup>2</sup> and in pregnant women it was  $0.597 \pm 0.048$  with no significant difference. BMD at proximal one third radius in controls was  $0.670 \pm 0.36$  g/cm<sup>2</sup> as compared to pregnant women where it was  $0.660 \pm 0.036$  and there was 1.5% increase in BMD in pregnant woman without any statistical significance. Total BMD at forearm in control and pregnant women were not significantly different and were  $0.586 \pm 0.035$  and  $0.582 \pm 0.036$  respectively ( $p=0.76$ ) (Table 2).

The mean serum calcium in pregnant women was  $2.28 \pm 0.065$  mmol/lit as compared to  $2.45 \pm 0.58$  mmol/lit in controls and was significantly lower ( $p = 0.001$ ). Mean serum albumin concentration in pregnant women was  $3.53 \pm 0.63$  mg/ dl as compared to  $4.78 \pm 0.43$  mg/ dl in controls and was significantly lower ( $p=0.003$ ).

**Table 1: Comparison of demographic profile.**

Sr. No.	Parameter	Pregnancy group N=32	Control group N=30	p value	t value
1	Age (year)	$25.62 \pm 4.35$	$25.20 \pm 4.77$	0.79	0.26
2	Height (meter)	$1.52 \pm 0.023$	$1.52 \pm 0.018$	0.80	0.26
3	Weight (kg)	$49.0 \pm 2.81$	$49.4 \pm 2.59$	0.84	0.25
4	BMI (kg/m <sup>2</sup> )	$21.46 \pm 0.99$	$21.32 \pm 1.11$	0.72	0.29
5	Parity	$1.0 \pm 1.39$	$1.2 \pm 1.47$	1.2	0.14
6	Duration of breast feeding (months)	$12 \pm 16.69$	$14.4 \pm 17$	0.69	0.39
7	Mean gestational age at the time of delivery (weeks)	$38.04 \pm 0.07$	-		
8	Mean infant birth weight (kg)	$2.57 \pm 0.84$	-		
9	Average daily calcium intake (mg/day)	1636	1598		

**Table 2: Comparison of mean bone mineral density of forearm.**

Sr. No.	Area of fore arm	BMD in pregnancy group (g/cm <sup>2</sup> )	BMD in control group (g/cm <sup>2</sup> )	p value	t value
1	Ultra distal radius	$0.431 \pm 0.058$	$0.437 \pm 0.049$	0.19	0.26
2	Mid radius	$0.597 \pm 0.048$	$0.599 \pm 0.051$	0.98	0.56
3	Proximal 1/3 <sup>rd</sup> radius	$0.660 \pm 0.036$	$0.670 \pm 0.036$	0.57	0.01
4	Total	$0.582 \pm 0.036$	$0.586 \pm 0.035$	0.76	0.29

**Table 3: Comparison of biochemical parameters.**

Sr. No.	Biochemical parameter	Pregnancy group N=32	Control group N=30	p value	t value
1	Serum calcium (m mol/lit)	$2.28 \pm 0.065$	$2.45 \pm 0.058$	0.001	7.55
2	Serum albumin (mg/dl)	$3.53 \pm 0.63$	$4.78 \pm 0.43$	0.003	2.30
3	Serum ALP (IU/L)	$184 \pm 66.4$	$73.5 \pm 45.7$	0.001	4.89
4	Serum TSH (m IU/L)	$1.83 \pm 1.99$	$1.46 \pm 1.01$	0.56	0.57

The mean serum alkaline phosphatase concentration in controls was  $73.5 \pm 45.7$  IU/lit as compared to pregnant women who has mean s. alkaline phosphatase  $184 \pm 66.4$  IU/lit. Mean s. alkaline phosphatase concentration in pregnant woman was statistically higher ( $p=0.001$ ) as compared to controls. Both controls as well as pregnant woman have serum TSH levels within normal limits and means serum TSH in controls was  $1.46 \pm 1.01$  mIU/lit as compared to  $1.86 \pm 1.99$  mIU/lit in pregnant woman without any statistical difference ( $p = 0.56$ ) (Table 3).

## DISCUSSION

Although DEXA scan of lumber region and hip is considered gold standard for non-invasive measurement of bone mineral density but these are not feasible in pregnant ladies. DEXA scan of distal forearm is a reasonably good alternative to estimate bone mineral content in pregnant women.<sup>4</sup> The results varied in different studies (Table 4).

**Table 4: BMD changes at forearm during pregnancy in different studies.<sup>4-13</sup>**

Author	BMD findings at forearm
Christiansen et al <sup>4</sup>	No significant change
Lamke et al <sup>12</sup>	4.2% fall in BMD at distal radius and ulna( $p<0.05$ ) 2% increase in BMD at proximal 1/3rd radius(Not Significant)
Drinkwater et al <sup>13</sup>	2.2% decrease in BMD of the radial shaft but not in distal part.( $p<0.05$ )
Kent et al <sup>7</sup>	No significant change
Cross et al <sup>8</sup>	No significant change
Kolthoff et al <sup>14</sup>	2% decrease at ultra-distal radius ( $p<0.001$ ) and no significant change at proximal one third radius
Lorreene et al <sup>9</sup>	No significant change
Naylor et al <sup>16</sup>	2.8% increase in BMD of arms ( $p = 0.01$ )
More et al <sup>17</sup>	Significant fall( $p<0.001$ ) of 3.8%.in BMD at ultra-distal radius and proximal one third radius
Ulrich et al <sup>15</sup>	1.2% increase at proximal 1/ 3'd radius ( $p<0.05$ ) 1.8% decrease at ultra-distal radius (Not Significant) No significant change in total BMD
Present study	1.4% decrease at ultra-distal radius (Not Significant) 1.5% increase at proximal one third radius (Not Significant) No significant change in total BMD

It was shown in the prior studies that peak bone mass is achieved in third decade of life and after that there is a gradual fall in the bone mass at the rate of 1-3% per decade of life till menopause and after menopause this

rate further increases. Some investigators found higher bone loss in adolescent mothers as compared to adults; as their own body requirement is high during adolescence.<sup>5</sup> While some other quoted that incidence of osteoporosis and osteopenia during pregnancy does not significantly increases with advancing age.<sup>6</sup> In present study there was 1.4% decrease in BMD at ultra-distal radius and 1.2% gain in BMD at proximal one third radius which were not statistically significant. There was no change in BMD at mid radius and in total BMD of forearm; the results being comparable to other studies.<sup>7-9</sup> Our results strengthen the assumption that increased demand of calcium during pregnancy is met mainly by increased calcium absorption rather than bone resorption. Kent et al found that there is increased intestinal 1,25-dihydroxyvitamin-D levels leading to enhanced absorption of calcium during pregnancy.<sup>7</sup> High levels of estrogen lead to increased bone formation during pregnancy and the pre-ovulatory rise of estrogen has been found to induce endosteal bone growth in animal studies. Slight non-significant increase in bone mineral at proximal third of the radius supports the hypothesis of building up of mineral stocks for future lactation; during pregnancy itself and this was also seen in animal models. Heaney et al, concluded that pregnancy appears to be a state of positive calcium balance.<sup>10</sup> Sowers et al, showed in a study that bone mineral density loss during lactation is recovered during pregnancy also in those who breast fed for prolonged period and got pregnant during lactational period, when bone mass was still low.<sup>11</sup> Insignificant fall in BMD at ultra-distal radius support the view that probably there is bone mineral redistribution during pregnancy and bone density decreases at trabecular bone and increases at cortical portion so that cortical thickness of the long bones increases during pregnancy. Many researchers also reported such site specific differences in bone mineral changes as we noticed in our observation.<sup>12-15</sup> Lamke et al, found that although trabecular bone constitutes only twenty per cent of the skeleton but it is more active metabolically and reflects changes in calcium metabolism earlier than cortical counterpart.<sup>12</sup> However many other researchers found significant decrease in bone mineral density at one or more sites of forearm in their research work.<sup>12-17</sup>

The mean serum calcium in pregnant women was  $2.28 \pm 0.065$  mmol/lit as compared to  $2.45 \pm 0.58$  mmol/lit in controls and was significantly lower ( $p=0.001$ ). There are a lot of studies on investigating markers of bone turnover showing that bone turnover is increased during pregnancy and especially during last trimester. These studies showed that total serum calcium concentration is significantly decreased during third trimester though ionized calcium concentration remains the same as in our observation. Speculation is that there is maximum calcium transfer through placenta to fetus occur during this period leading to this decrease. This fall could be because of lowered serum albumin concentration which usually occurred during pregnancy and also seen in our results. Results of present study were consistent with

results of Lorrene et al, who found significantly lowered serum calcium ( $p<0.05$ ) at the end of second and third trimester and nadir at the end of second trimester.<sup>9</sup> Ulrich and coworkers found that the increase in bone resorption was accompanied by a significant ( $p<0.002$ ) decrease in serum calcium within the normal reference range in the third trimester.<sup>15</sup> It is assumed that the calcium transfer to the fetus also peaks in the last trimester.<sup>18</sup> Therefore, they speculated that the maternal serum calcium is decreased due to placental transport. In contrast More et al, Zeni et al found no significant difference in their studies.<sup>17,19</sup>

Mean serum Alkaline phosphatase concentration in pregnant woman was statistically higher ( $p=0.001$ ) as compared to controls. The increase in serum total alkaline phosphatase concentration during pregnancy has been shown by other investigators as well.<sup>16-18,20,21</sup> Some researchers found linear increase while other found biphasic increase. Ulrich et al, showed a biphasic pattern with decrease from base line to first trimester followed by a significant increase in the third trimester and post-partum.<sup>15</sup> This being cross sectional we could not tell the pattern of rise. The result of the present study agreed well with the cross et al, they found that ALP was significantly higher ( $p=0.001$ ) especially during third trimester.<sup>8</sup> Valenzuela reported an increase in bone specific alkaline phosphatase as early as by 10-12 weeks of gestation.<sup>20</sup> In agreement to present study Zeni et al, found that serum alkaline phosphatase was increased significantly during last two trimesters and highest increment was observed during third trimester.<sup>19</sup>

## CONCLUSION

Osteopenia and osteoporosis are the major bone morbidities in women and these morbidities usually occur after menopause. Pregnancy is the state of high bone turnover. Bone mineral densitometric studies provide an opportunity to study the contribution of pregnancy to bone morbidities and to assess the preventive measures.

The present study concludes that bone mineral density did not decreased significantly during pregnancy and there is no apparent effect of pregnancy on bone mineral content. To further confirm the role of pregnancy on bone mineral reserve; it is needed to evaluate the serial BMD thoroughly at other sites also, and to comment upon whether these changes in BMD are transient or permanent, more extended period of study is required and it is suggested that the bone mineral contents to be measured at multiple sites longitudinally from pre-pregnancy till post-weaning, when all the possible hormonal changes have been settled.
