ABSTRACT

Background: Prolonged pregnancy has always been regarded as a high-risk condition because perinatal morbidity and mortality is known to rise. The interest in postdatism (just beyond expected date of delivery) has been recent and the management is controversial, more so with the advent of sonography providing information about placental aging and amount of amniotic fluid. The aim of the present retrospective study was to analyze the outcome of pregnancies which crossed the expected date of delivery.

Methods: The present study was a cross sectional observational study, conducted between April 2018 to September 2018, among 90 cases presented with post dated pregnancy under the department of obstetrics and gynecology, in a tertiary medical teaching institute in Maharashtra.

Results: Maximum number of cases, i.e., 22.22% indications were meconium stained liquor with fetal distress, in 18.51% cases indications were failure of induction, in 22.22% indications were nonreactive NST, in 17.61% cases indications were CPD.

Conclusions: It was concluded that prolonged pregnancy was associated with significant risk of perinatal complications such as fetal distress, meconium aspiration syndrome and IUGR.

Keywords: Maternal morbidity, Obstetric complications, Postdated pregnancy, Prolonged pregnancy, Perinatal complications

INTRODUCTION

Postdate, post-term, postmaturity and prolonged pregnancy is accepted terms by WHO and the International Federation of Gynecology and Obstetrics to describe pregnancy beyond dates (expected date of delivery). As per WHO, post-term pregnancy (PTP) is defined as a pregnancy that persists beyond 294 days or 42 weeks of gestation. The reported frequency of PTP is approximately 7%. The incidence of PTP varies depending on whether the calculation is based on the history and clinical examination alone, or whether early pregnancy ultrasound examination is used to estimate gestational age. The assessment of the gestational age by early ultrasound examination has reduced the “incidence” of PTP by 50.0%. The most cases of PTP result from a prolongation of gestation. Other cases result from an inability to accurately define estimated date of delivery. Complications to both mother and fetus are seen in postdated pregnancies. It has been reported that in a pregnancy which has crossed the expected date of delivery; there is an increased risk of oligohydramnios,
meconium stained amniotic fluid, macrosomia, fetal postmaturity syndrome, and caesarean delivery, all of which jeopardize the baby as well as the mother.

Prolonged pregnancy has always been regarded as a high-risk condition because perinatal morbidity and mortality is known to rise. The interest in postdatism (just beyond expected date of delivery) has been recent and the management is controversial, more so with the advent of sonography providing information about placental aging and amount of amniotic fluid. The aim of the present retrospective study was to analyze the outcome of pregnancies which crossed the expected date of delivery.

METHODS

The present study was a cross sectional observational study, conducted between April 2018 to September 2018, among 90 cases presented with post dated pregnancy under the department of obstetrics and gynaecology, in a tertiary medical teaching institute in Maharashtra. The present study includes both primigravida and multigravida beyond 40 weeks of gestation.

Sampling technique used in this study was non random sampling (purposive) method.

Inclusion criteria

Pregnant women more than 40 weeks of gestation (last three menstrual cycles regular, not used contraceptive pills for the past 3 months, not conceived during lactational amenorrhea), singleton pregnancy with cephalic presentation were included in the present study.

Exclusion criteria

Any associated complications such as previous Lower Segment Cesarean Section (LSCS), malpresentations, placenta previa, abruption, PIH, gestational diabetes anemia and other medical complications, Fetal anomalies were excluded from the present study.

The data was collected with the help of standard, semi structured, pre validated case record proforma. The data was entered with the help of Microsoft Excel spreadsheets. The data was analysed using SPSS software version 21. Statistical analysis was performed using descriptive statistics, frequencies and the data was arranged in tables and charts.

RESULTS

In the present study, it was observed that maximum 56.66% cases were belonged to age group 20 - 25 years, 38.88% cases were of age group 26-30 years, and only 4.44% cases were of age group 31-35 years mean±standard deviation 24.27±3.15 (Table 1).

In the present study, it was assessed that the ANC registration status of the study subjects according to the current national registration systems, we observed that 75.55% of the pregnancies were registered and 24.44% were unregistered cases (Figure 1).

In the current study, majority of the cases were primigravida (63.33%) while 36.66% cases were multigravida (Figure 2).

A total number of full term normal vaginal deliveries were conducted among 70% cases, whereas lower
In the present study, maternal complications due to post
dated pregnancy were assessed, it was observed that
oligohydramnios was reported among 20% cases, perineal
tear was observed among 6.66% cases, atomic
PPH in 3.33% cases, and shoulder dystocia in 4.44% cases
(Table 4). Prolonged delivery was associated with increased
risks of maternal and perinatal complications,
hence the rate of caesarean section was higher in
prolonged pregnancies.

DISCUSSION

In the present study, it was observed that maximum
56.66% cases were belonged to age group 20-25 years,
38.88% cases were of age group 26-30 years, and only
4.44% cases were of age group 31-35 years mean ±standard deviation 24.27±3.15. While the mean age in
Mahapatro’s study was 24.19±3.30, while the mean age
in Eden et al. study was 25.8 years.13 In the study,
majority cases were primigravida (62%) which is similar
to Mahapatro and Alexander et al. study.9

A total number of full term normal vaginal deliveries
were conducted among 70% cases, whereas lower
segment caesarean section was performed among 30% of

segment caesarean section was performed among 30% of
the study subjects (Table 2). Maximum number of cases,
i.e., 22.22% indications were meconium stained liquor
with fetal distress, in 18.51% cases indications were
failure of induction, in 22.22% indications were
nonreactive NST, in 17.61% cases indications were CPD,
in 14.81% cases indications were non-progress of labor,
and in 3.7% cases indications were cervical dystocia
(Table 3).

</tr>
</tbody>
</table>

In the present study, it was observed that Meconium stained
liquor with fetal distress is the most common indication
for LSCS like Mahapatro’s study, in which fetal distress
was found to be the most common indication for LSCS
(65.5%).9

Prolonged delivery was associated with increased risks of
perinatal complications such as fetal distress and
meconium aspiration syndrome. The rate of caesarean
section was higher in prolonged pregnancies.

The timely onset of labor and birth is an important
determinant of perinatal outcome. Most pregnancies
undergoing postterm induction are not post-term when
assessed by ultrasound dates. Regardless of whether
prolonged pregnancy is considered to be a risk factor
requiring intervention, the proportion of pregnancies
considered “post-term” can be reduced considerably by a
dating policy which ignores menstrual dates and
establishes the expected delivery date on the basis of
ultrasound dates alone.

Management of postdated pregnancy is a challenge to
obstetrician and a careful advice and monitoring can
alleviate maternal anxiety and untoward complications.

Pregnancy beyond 40 weeks needs frequent amniotic
fluid index monitoring as in the study we found more
cases of oligohydramnios. In the study, we observed
pregnancy beyond 41 weeks increases rate of caesarean
section and NICU admission.

CONCLUSION

Prolonged pregnancy was associated with significant risk of
perinatal complications such as fetal distress,
meconium aspiration syndrome and IUGR.

There was significantly increased the risk of obstetric
complications such as oligohydramnios, perineal tear,
atonic PPH and shoulder dystocia.

The adverse outcome can be reduced by making accurate
gestational age and diagnosis of postterm gestation as
well as recognition and management of risk factors.
