ABSTRACT

Background: Cancer of cervix ranks as the third common malignancy in females worldwide. In developing countries like India, carcinoma cervix is the second commonest malignancy affecting females. In India, every year 1,26,000 new cases are identified and 67,477 deaths occur due to cervical carcinoma. Cervical carcinoma affects women of age 15-44 years and disease peaks at 55-66 years. On average, Indian women have a 2.5% risk of developing carcinoma cervix. It was estimated worldwide that every 5th woman, who suffer from cervical cancer belongs to India.

Methods: A comparative study which included 110 married women of age 20 to 65 years. Women who presented with white discharge, lower abdominal pain, post coital bleeding and post-menopausal bleeding were subjected to Pap smear and colposcopy guided biopsy.

Results: A total 53.6% women had inflammatory smear, followed by 34.5% women with normal Pap smear, 0.1% women had bacterial vaginosis, 6.4% women had LSIL and 4.5% women had HSIL. Authors found that 63.6% women had chronic cervicitis. 15.4% had chronic endo papillary cervicitis, 13.6% had CIN 1, 5.4% women had CIN 2 and 1.8% women had squamous cell carcinoma. Association of Pap smear with histopathology is statistically significant (p value <0.001).

Conclusions: Pap smear can be used as screening test for detecting premalignant lesions of cervix. Colposcopy guided cervix biopsy has got better specificity than Pap smear, so all symptomatic women should be subjected to colposcopy guided cervix biopsy to detect carcinoma at early stage.

Keywords: Cervical carcinoma, Colposcopy guided biopsy, Pap smear

INTRODUCTION

Cancer of cervix ranks as the third common malignancy in females worldwide. In developing countries like India, carcinoma cervix is the second commonest malignancy affecting females. India accounts for 18% of the global burden of carcinoma cervix.

In India, every year 1,26,000 new cases are identified and 67,477 deaths occur due to cervical carcinoma. Cervical carcinoma affects women of age 15-44 years and disease peaks at 55-66 years. On average, Indian women have a 2.5% risk of developing carcinoma cervix. It was estimated worldwide that every 5th woman, who suffer from cervical cancer belongs to India.

According to WHO, 80% of death from carcinoma cervix is from developing countries. In India, carcinoma cervix plays a major role in mortality and morbidity of patient. In developing countries like India, more than 70% of the population lives in rural areas. Rural Indian women undergo early marriage, multiple childbirth, poor nutrition status and they lack awareness about contraception, availability of screening programmes and therefore are prone to acquire carcinoma cervix. According to a survey conducted by NFHS -2, only 30%
of rural women are exposed to newspaper and television. Until rural women develop awareness about screening programs, it is very difficult to prevent carcinoma cervix.²

Cervical cancer is a malignancy that has got a long latent period to transform into invasive carcinoma, so if women undergo screening at an early stage of disease, invasive lesion of cervix can be prevented.³ More than 80% of women with cervical carcinoma present with advanced stage of disease, due to their lack of health education, awareness of screening programs and lack of accessibility to medical services.⁴ The most common type of carcinoma of cervix is squamous cell carcinoma. Nowadays, adenocarcinoma is on the rise due to increased use of oral contraceptives. Most common cause of cervical carcinoma is human papillomavirus (HPV). Subtypes HPV-16 and HPV-18 are involved in almost 99% of invasive lesion of carcinoma cervix.⁵

Cervix is easy for accessibility. Cervical epithelial cells have got potential to change to dysplasia and invasive carcinoma. Premalignant lesions of cervix had got long latent period. Hence, women should undergo screening regularly to detect premalignant lesions of the cervix.⁶

Papanicolaou (Pap) smear is a simple, cheap and non-invasive method used for screening of carcinoma cervix, with specificity of 94% and sensitivity of 72%.⁷

**METHODS**

Married women aged 20-65 years attending gynecology OPD of Shri Sathya Sai Medical College and Research Institute, a tertiary care hospital in Kancheepuram district, Ammapettai in Tamil Nadu South India. This was 18 months study. Quasi experimental study conducted at Shri Sathya Sai Medical College and Research Institute, a tertiary care hospital, Ammapettai in Tamil Nadu, South India.

**Inclusion criteria**

- Married women between ages of 20-65 year’s
- Women with symptoms like vaginal discharge, postcoital bleeding, post-menopausal bleeding, persistent leukorrhea.

**Exclusion criteria**

- Unmarried women
- Pregnant women
- Women with frank lesion and active infection
- Women below age of 20 years and women above 65 years.

Sample size was calculated based on the study by Kalyankar et al.³

Formula used in determining sample size is N- 4PQ/(L)², where P is prevalence is 80%

Q is 100-P=20
L is 10% error of prevalence
L= 4×80×20/(8)² = 6400/64 = 100
(10% non-response error is 10%)
= 100+10
= 110

**Methodology**

A total 110 patients satisfying inclusion criteria will be included in the study of age group 20-65 years. An Informed written consent shall be taken from all the subjects. Detailed history regarding age, age at marriage, age at first pregnancy, parity, menstrual history, presenting symptoms will be asked. Through speculum examination, Pap smear will be taken. Using colposcopy, colposcopy guided biopsy will be taken. Staining will be done with universal stain for cytological preparations. Papanicolaou stain is Harris haematoxylin the optimum nuclear stain and combination of OG6 and EA 50. Bethesda classification will be used for reporting.

Colposcopy on a rolling stand was used with a focal length of 300 nm. It is a microscope which consist of the binocular head with eye piece the main objective, microscope tilt, and illuminating system with built in filters. Green filter serves to enhance the fine details of vascular pattern of the target epithelium. The light source on colposcope is halogen. Colposcopic signs were scored under Reid colposcopic index in following categories:

- Sharpness of margin
- Epithelial colour
- Vascular pattern
- Iodine staining.

Each category was given three points.

**Statistical analysis**

Data was entered into Microsoft excel and SPSS (Statistical package for social science) version 23.0 was used for descriptive statistics. Categorical data was analysed using percentage. Inferential statistics was analysed using Chi-square test. The probability value of <0.05 was considered as statistically significant.
RESULTS

In this study, 42.7% women belong to age group 31-40 years, 30.9% women belong to 41-50 years of age, 14.5% women belong to 20-30 years of age, 9.1% women belong to 51-60 years of age and 2.7% women are more than 60 years of age. In this study 38.2% women were para 3, 33.6% women were para 4, 15.5% women were para 5, 6.45% women were para 2, 4.5% women were para 6 and 1.8% women were primipara.

In this study population, white discharge was the most common chief complaint (46.4%), followed by lower abdominal pain in 24.5%, low back ache in 10.9%, postcoital bleeding in 10% and postmenopausal bleeding seen in 8.2%. Majority of women (63.6%) had their first child before 20 years of age, 30% women had their first child between 21-30 years and 6.4% women had their first child between 31-40 years of age.

In this study, 53.6% women had inflammatory smear, followed by 34.5% women with normal Pap smear, 0.1% women had bacterial vaginosis, 6.4% women had LSIL and 4.5% women had HSIL. In this study, authors found that 63.6% women had chronic cervicitis, 15.4% had chronic endo papillary cervicitis, 13.6% had CIN 1, 5.4% women had CIN 2 and 1.8% women had squamous cell carcinoma. In this study, association of Pap smear with histopathology is statistically significant (p value <0.001) (Table 1).

DISCUSSION

This study included 110 women in which 42.7% women belonged to age group 31-40 years, which is comparable to the study by Kalyankar et al (39.7%), Shaki et al (44.4%) and Thobbi VA et al (35%). In the studies done by Vincent et al and Sathiyakala et al, 26.5% women and 20% women belonged to the same age group, respectively. The findings in their studies could be different from the present study because their study sample was more compared to this study.

In this study, 22.72% of women in the age group of 31-40 years had inflammatory Pap smear. In the age groups, 31-40 years, 41-50 years and 51-60 years, LSIL was found in 1.8 % of women in each age group.

In the age groups, 41-50 years and 51-60 years, HSIL was seen in 1.8% of women in each age group. Also, 1.8% (2 women) had squamous cell carcinoma in this study. In these two women, one belonged to the age group 41-50 years and another woman belonged to the age group 51-60 years. Both these women were multiparous, had early marriage and belonged to low socio-economic class. Thus, these two women had multiple high-risk factors for developing carcinoma cervix.

In this study, 44.4%) and Thobbi VA et al (35%).

In this study, 38.2% women were multiparous, which is comparable to the study by Kalyankar et al in which, 38.2% women were multiparous. In contrast, in studies done by Shaki et al, Arya et al and Parveen et al, 16.4%, 78% and 23% of women were multiparous, respectively.

In this study, white discharge was the most common complaint (46.4%), followed by lower abdominal pain (24.5%), postcoital bleeding (10%) and post-menopausal bleeding (8.2%), which is similar to the study by Kalyankar et al and Garg et al. In another study done by Shaki et al, white discharge was seen in 36.5%, postcoital bleeding in 3% and postmenopausal bleeding in 5%. Similarly, in a study by Sachan et al, white discharge was seen in 36.96%, abdominal pain in 25.6%, postcoital bleeding in 3.09% and postmenopausal bleeding in 1.45%. Vincent et al observed that white discharge was seen in 30.21%, abdominal pain in 17.73% and post-menopausal bleeding in 1.25% whereas Manjit et al observed bleeding per vaginum in 79.1%, white discharge in 8.3% and abdominal pain in 4.1%. These
variations could be due to differences in ethnicity and study population.

In this study, 2 women (1.8%) had carcinoma cervix. They were multiparous women, belonging to low socio-economic group. Among them, one woman presented with post coital bleeding and other women presented with postmenopausal bleeding. These are the most common symptoms of carcinoma cervix.

In this study, on per speculum examination, 29.1% of women had white discharge, followed by cervical erosion in 19.1%, hypertrophied cervix in 18.2%, congested cervix in 14.5%, cervical erosion that bleeds on touch in 11.8% and cervix with foul smelling discharge that bleeds on touch in 7.3% women. These findings were different from the study by Shaki et al, in which white discharge was seen in 56%, cervical erosion in 15.5%, cervix that bleeds on touch in 2%. A study by Kalyankar et al, found cervical erosion in 30.61%, ectropion in 14.28%, congested cervix in 6.12% and leukoplakia in 1.02%. In another study done by Saleh et al, they found ectropion in 36%, cervicitis in 18.90%, hypertrophied cervix in 14.90%, cervix that bleeds on touch in 14.90%. These differences could be due to variation in observers, interpretation errors and large sample size.

In this study, on Pap smear examination, authors found that 34.5% had normal Pap smear, 53.6% had inflammatory Pap smear, 0.1% had bacterial vaginitis, 6.4% had LSIL and 4.5% had HSIL, while in a study by Shaki et al, 2 women (1.8%) had carcinoma cervix. In the age group of 31-40 years, 41-50 years and 51-60 years, LSIL was seen 1.8%. In the age group of 41-50 years, HSIL was seen in 1.8% of women. In contrast to this study, Vincent et al found that 44.44% had LSIL in the age group of 50-59 years and 36.36% had HSIL in the age group of 40-49 years. In a study by Thobbi et al, 33.7% and 57.9% of women belonging to 35-39 years had inflammatory smears and LSIL respectively, and 1.5% of women belonging to 40-45 years had HSIL. Sachan et al, found that 48.8% of women had normal smear, 42.6% had inflammatory smear, 5.09% had LSIL and 0.48% had HSIL. These findings in the studies are different, which could be due to variation in observers and differences in interpretation of results. Also, these variations may be due to the larger sample size in their study.

ACKNOWLEDGMENTS

Authors would like to thank dean, Dr. Sukumaran Annamalai, Shri Sathyai Sai Medical College and Research Institute, Kancheepuram district, for granting me permission to carry out this study. Authors would also thanks to take this opportunity to convey my heartiest gratitude and sincere thanks to Co-guide Dr. Dost Mohammed Khan, MD professor and HOD, department of pathology, Shri Sathyai Sai Medical College and Research Institute, who with their vast knowledge and professional expertise have provided with guidance and constant encouragement throughout the course of this study and in the preparation of this dissertation. Authors extend their sincere gratitude to Dr. K. Sivankumar, professor and HOD of obstetrics and gynecology.
